About the probability structure of Brun's Algorithm in dimension two

└

BERNHARD SCHRATZBERGER¹ <bernhard.schratzberger@sbg.ac.at>

We describe the probability structure of the digits of Brun's Algorithm in dimension two. When viewed as doubly infinite sequences of random variables (defined on a natural extension), the digits can be seen as an example of an infinite order chain in the theory of dependence with complete connections. As a consequence, we show fast convergence of Lebesgue measure λ to the invariant measure γ , transferring the method of Paup Lévy 1929. We thus clarify the role of the dual algorithm in the method.
